Sensory Processing

- Sensory processing begins when primary afferents carry touch signals to the spinal cord
- In the SDH signals are processed by interneurons before being relayed to the brain by projection neurons

Spinal Dorsal Horn

- The SDH relies on multiple cellular- and circuit-level mechanisms to correctly process sensory input

Chronic Pain

- In chronic pain conditions there is abnormal processing of touch signals
- Improved clinical treatments are hindered by incomplete understanding of higher-level sensory processing

Problem: We need to investigate the network-level consequences of disinhibition

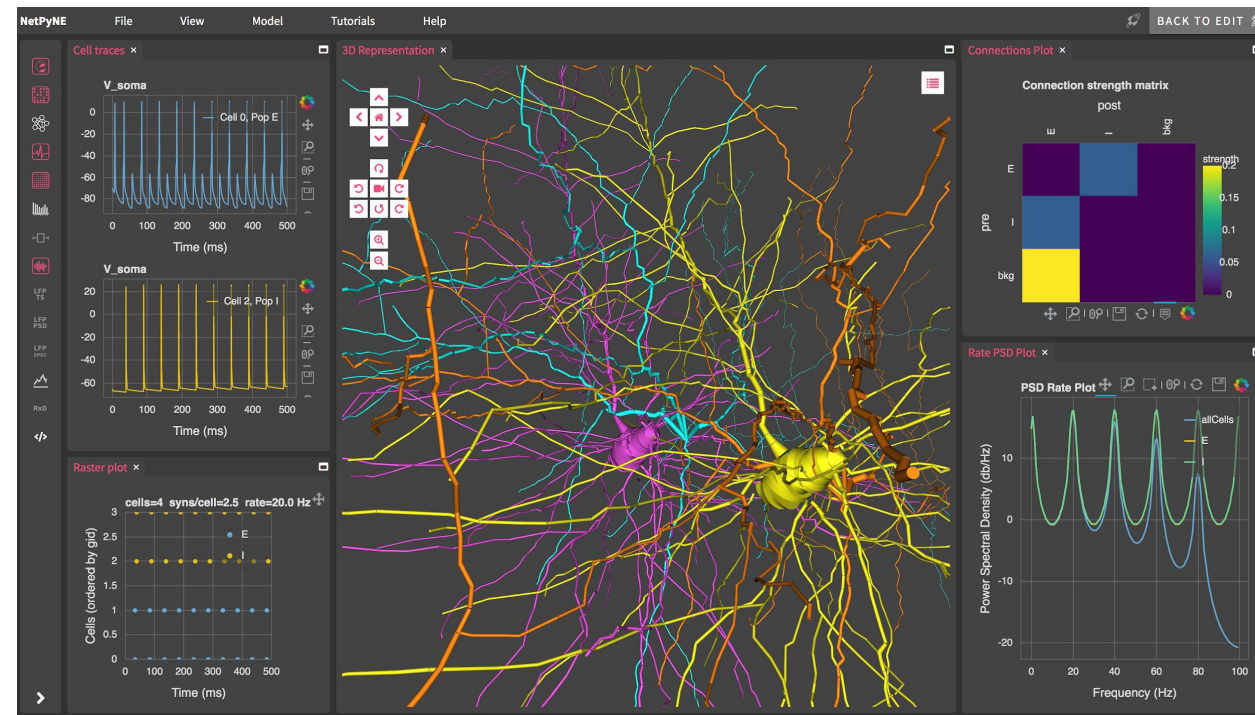

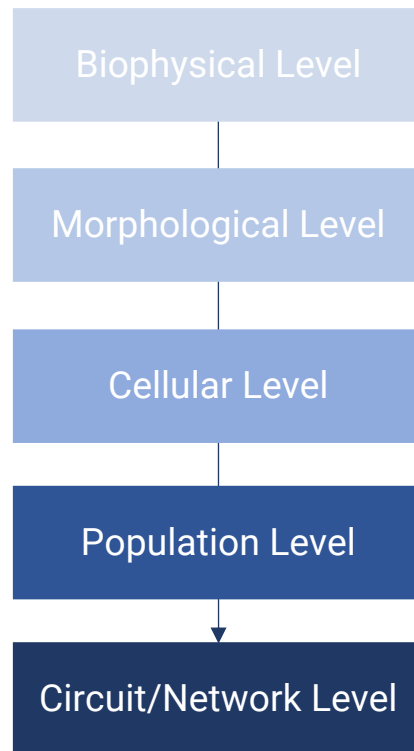

- Probing the SDH is difficult to do experimentally due to its immense complexity

Solution: We built a multiscale model of the SDH and simulate disinhibition

- Link the molecular-, cellular-, and network-level properties underlying chronic pain

NetPyNE

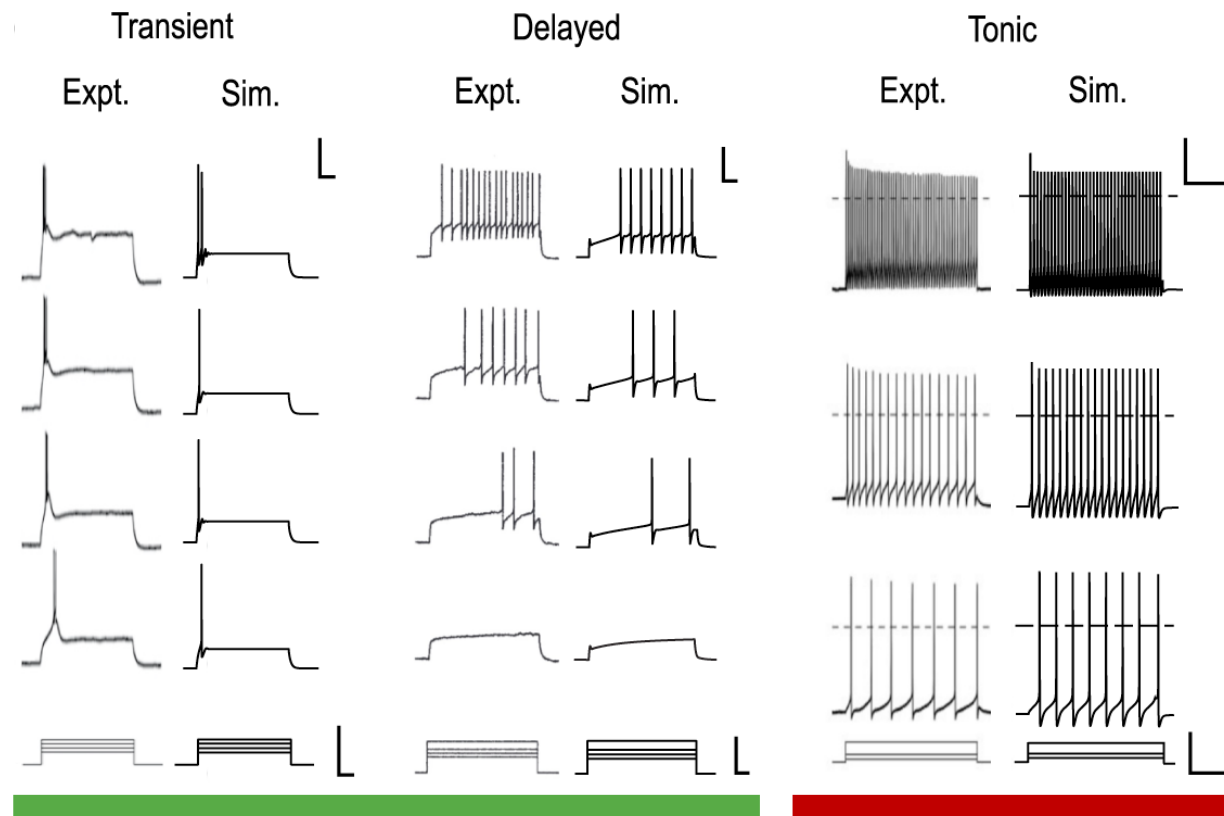

- We developed the network using NetPyNE, a Python package that helps facilitate the development, simulation, and analysis of multiscale network models in NEURON

Dura-Bernal et al. (2019)

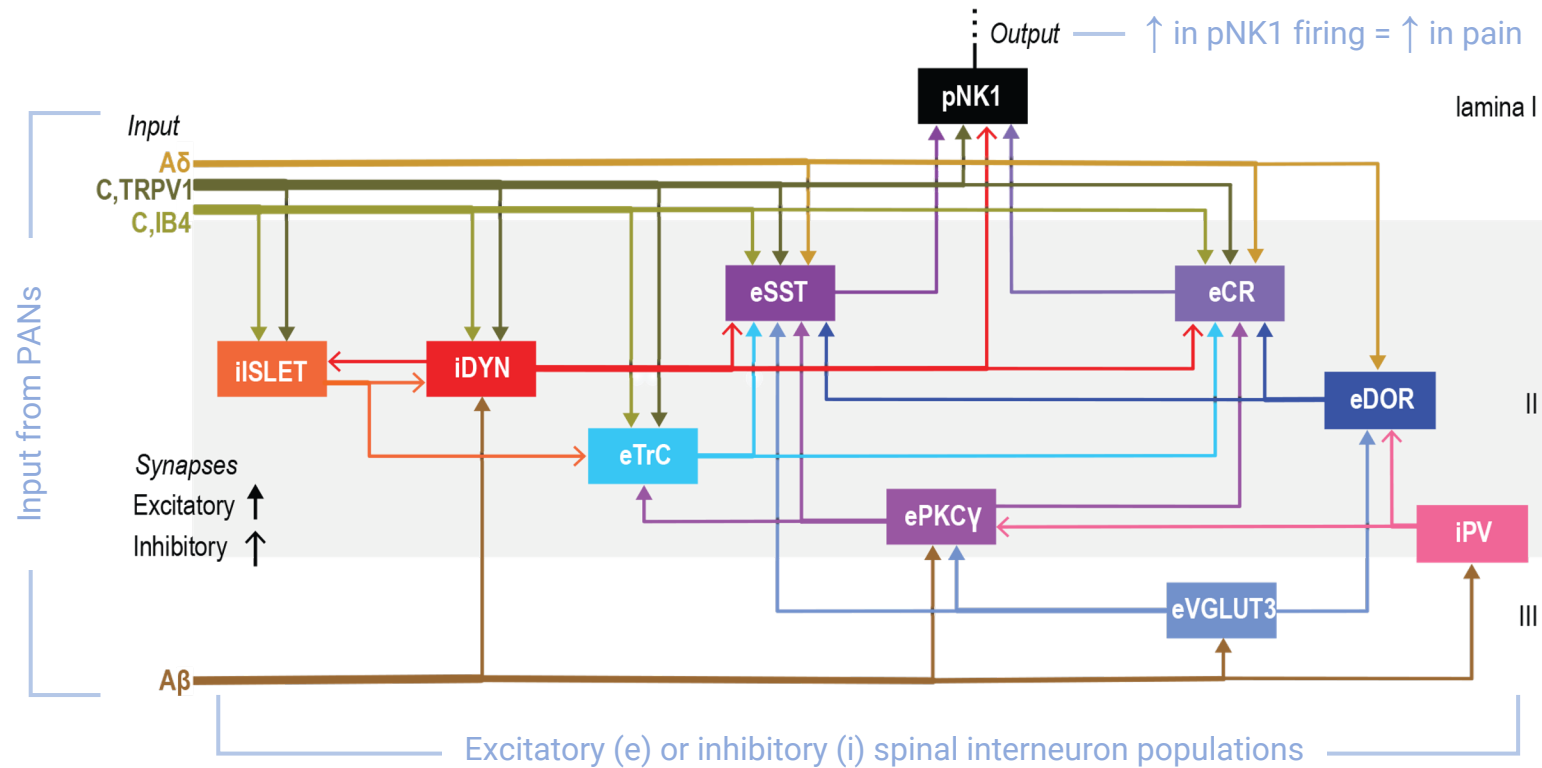

Spinal Neuron Models

- Conductance-based models were tuned to match electrophysiology recordings from spinal neurons

Circuit Connectivity

- The model circuit was designed based on experimentally-derived SDH connectivity

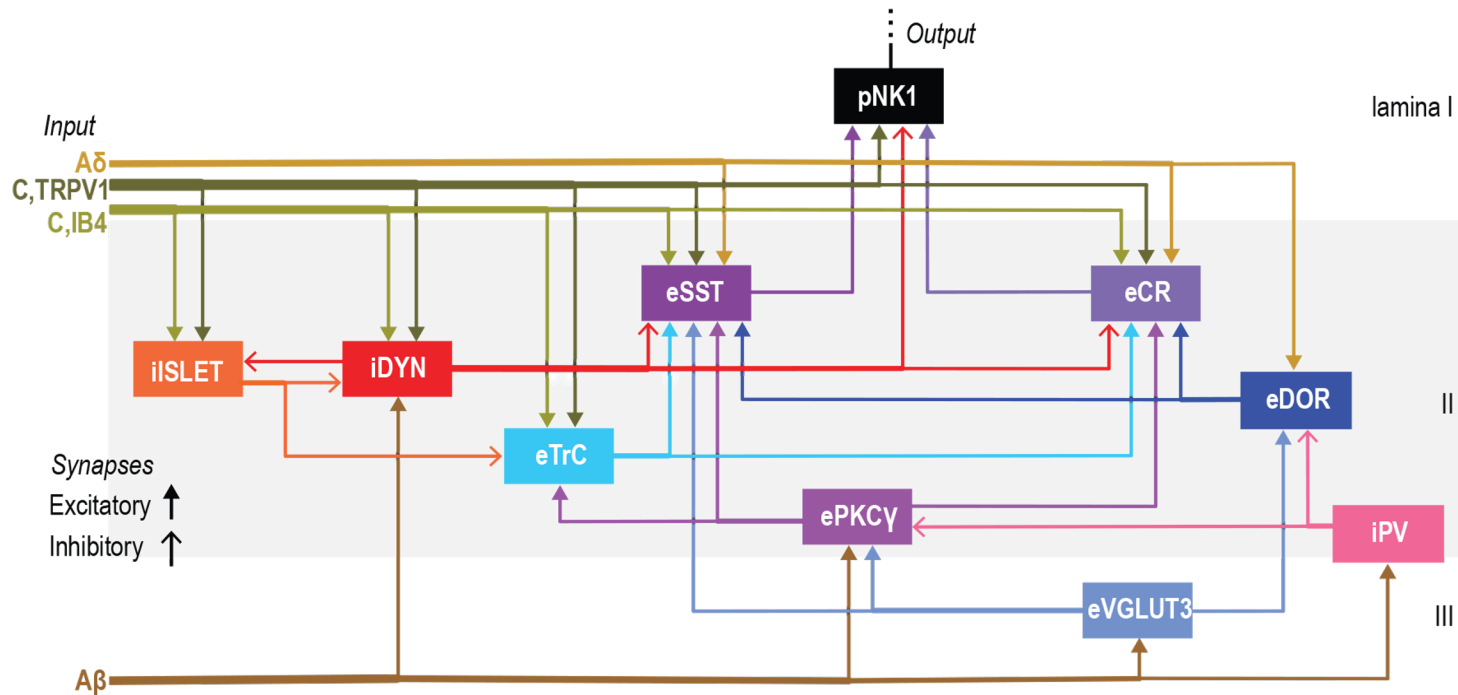

Experimentally dissected using:

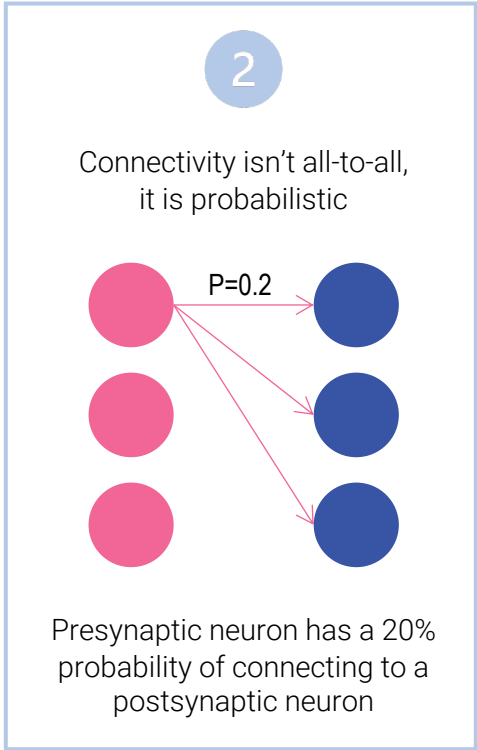

- Paired recordings
- Genetic labeling
- Optogenetics
- Ablation studies

Circuit Connectivity

- Variability in circuit output (e.g. across pNK1 spike trains) is influenced by...

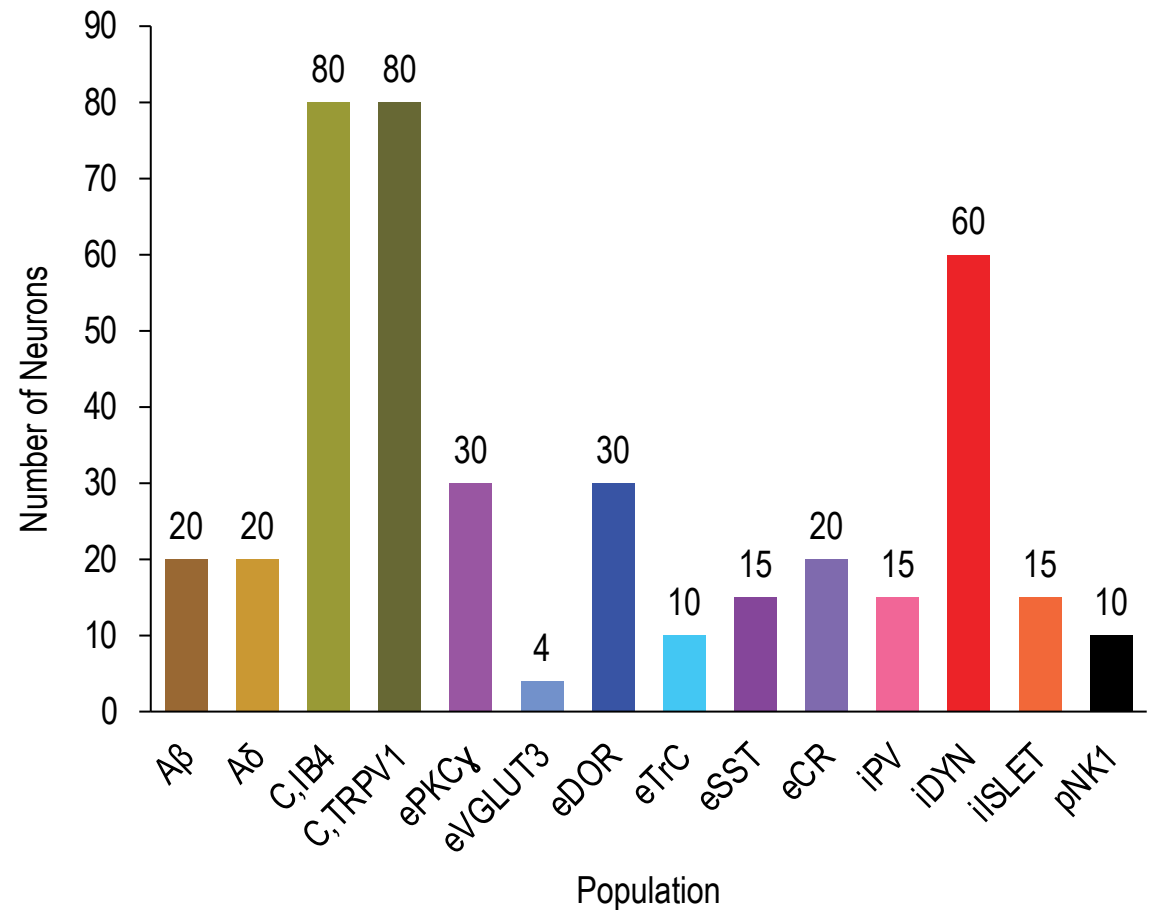

1
Input modeled as Poisson processes

Population Size

- A total of 409 neurons were simulated across 15 different populations.
- Numbers of neurons in each population were mainly approximated from immunohistochemical data.
- The number of neurons were scaled down to 20% to reduce computing load.

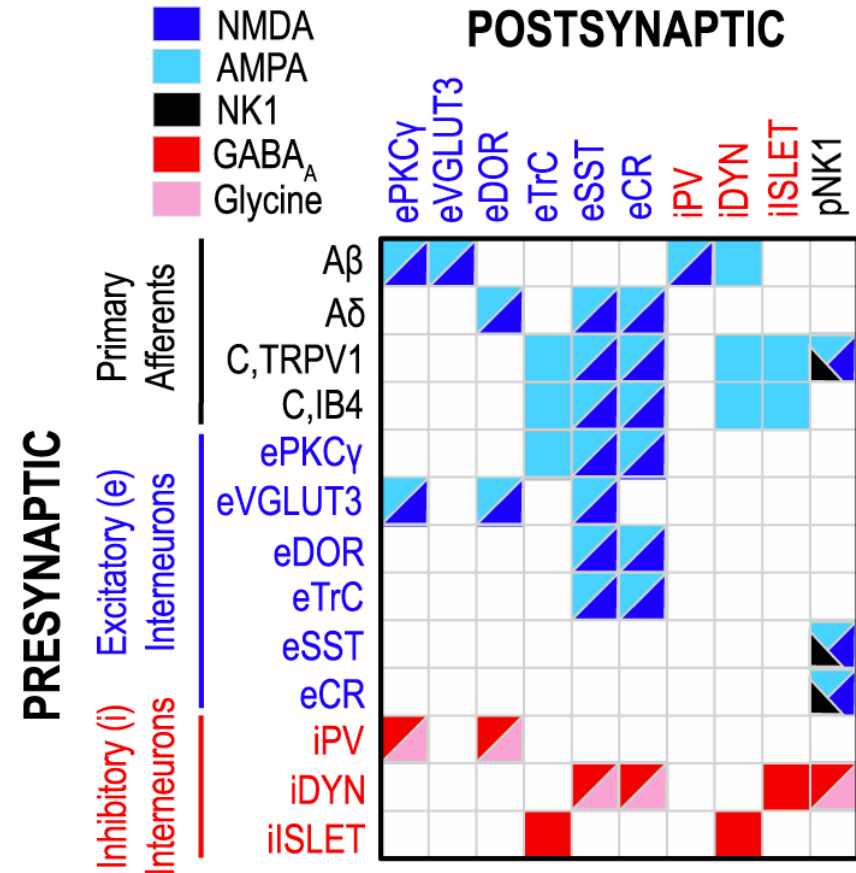

(Le Bars et al. 2001, Häring et al. 2018)

Synapse Models

- Excitatory synaptic transmission was mediated by AMPA, NMDA, or NK1 receptors.
- Inhibitory synaptic transmission was mediated by GABA_A or glycine receptors.
- Synapses were modeled using Exp2Syn and scaled by a synaptic weight.

$$I_{syn} = g_{syn} \times (V - E_{ion})$$

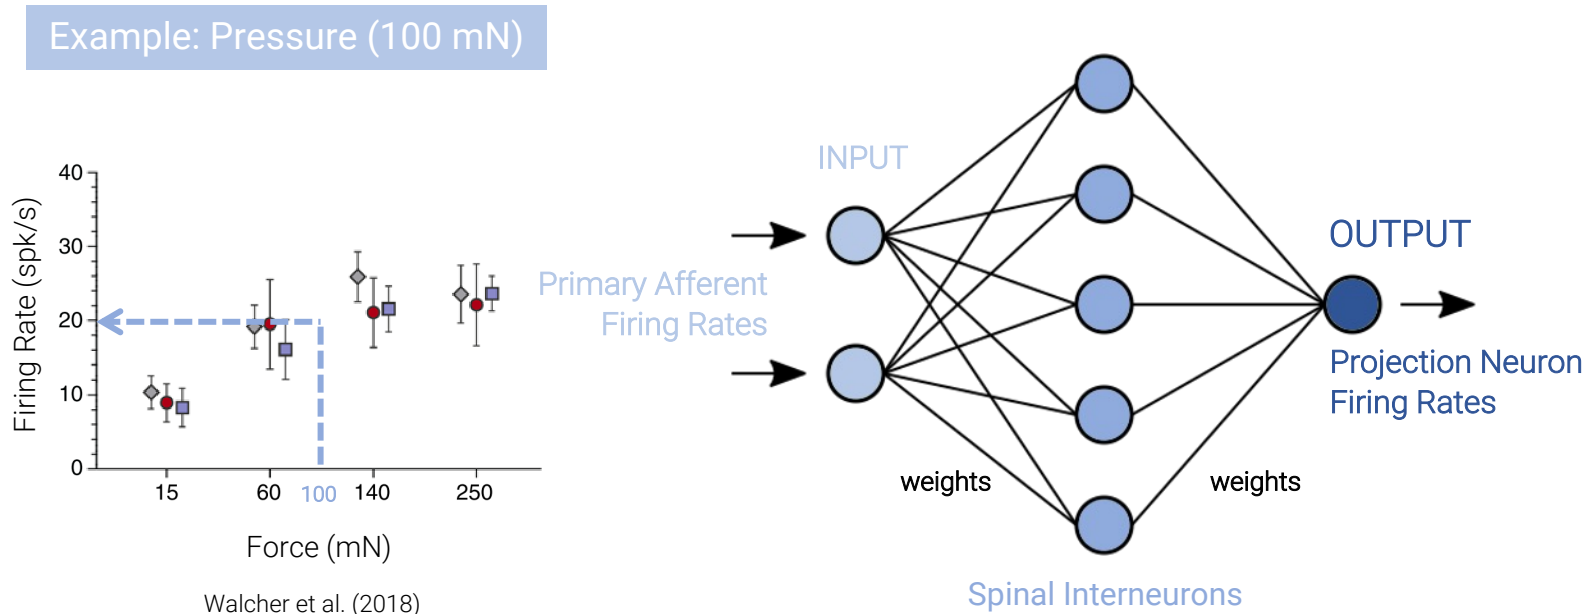

$$g_{syn} = weight \times \left(e^{\frac{-t}{\tau_2}} - e^{\frac{-t}{\tau_1}} \right)$$

N=35 synaptic weights

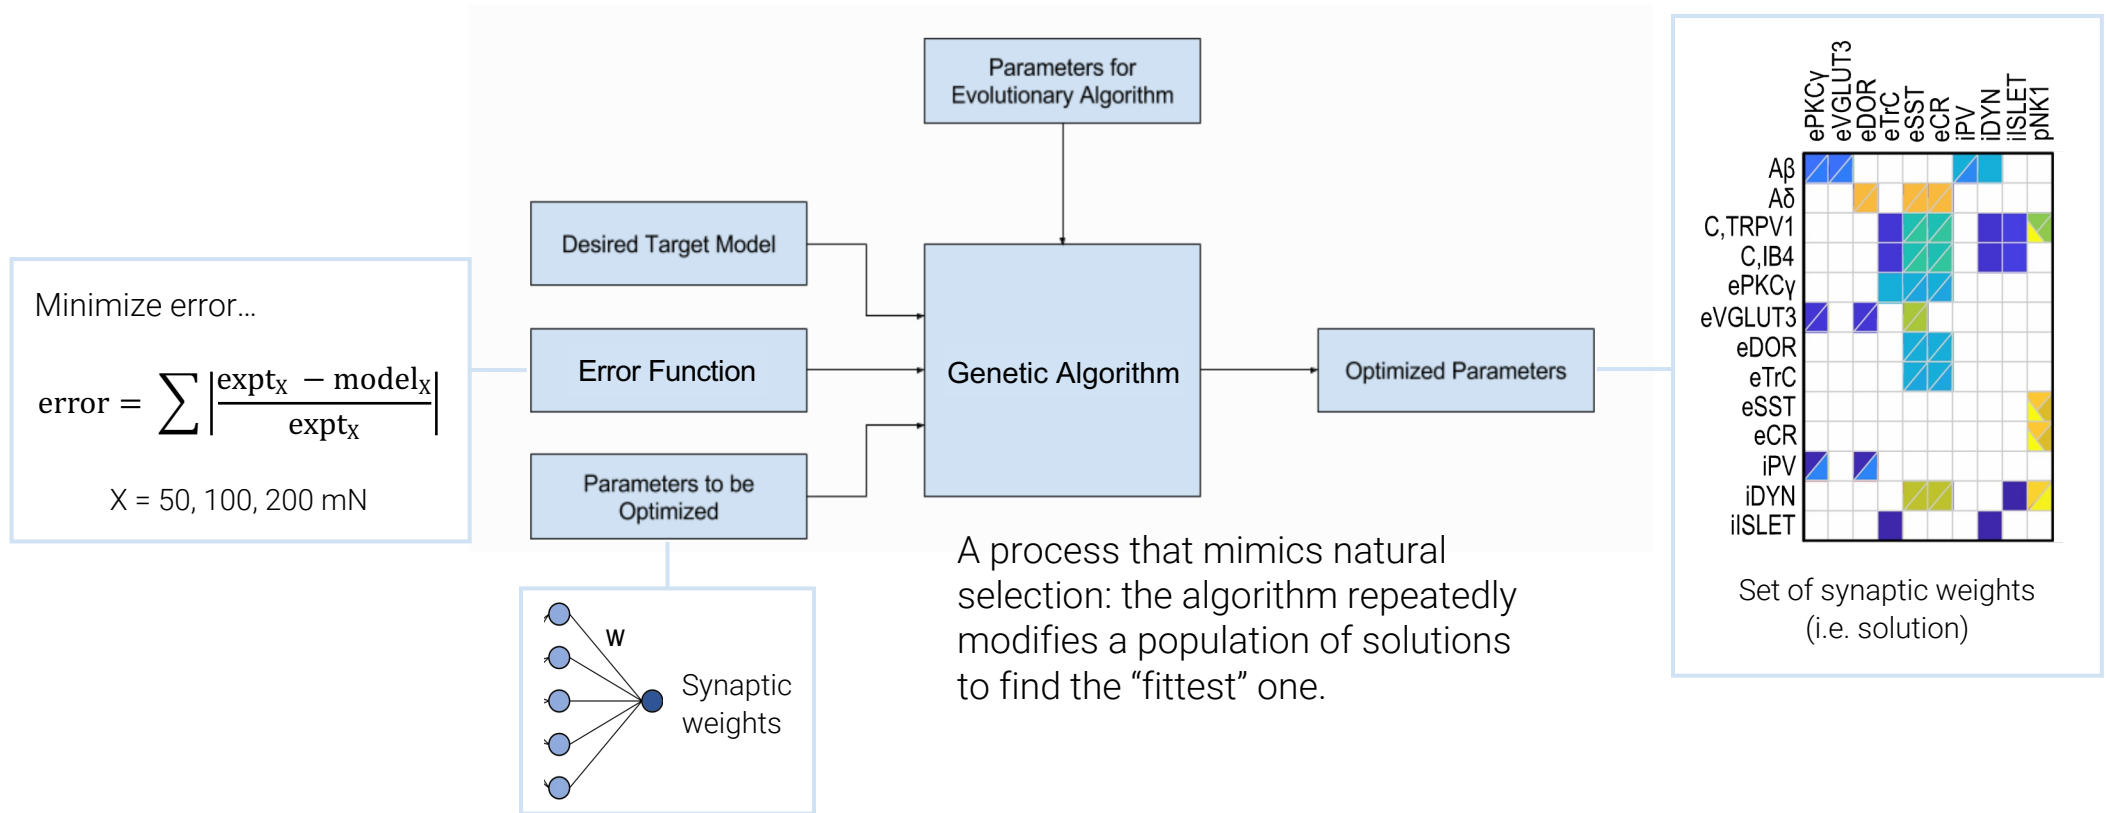

Fitting the Model to Experimental Data

- Synaptic weights were optimized so that primary afferent input produced projection neuron output in response to the same experimental stimulation.

Optimizing Synaptic Weights

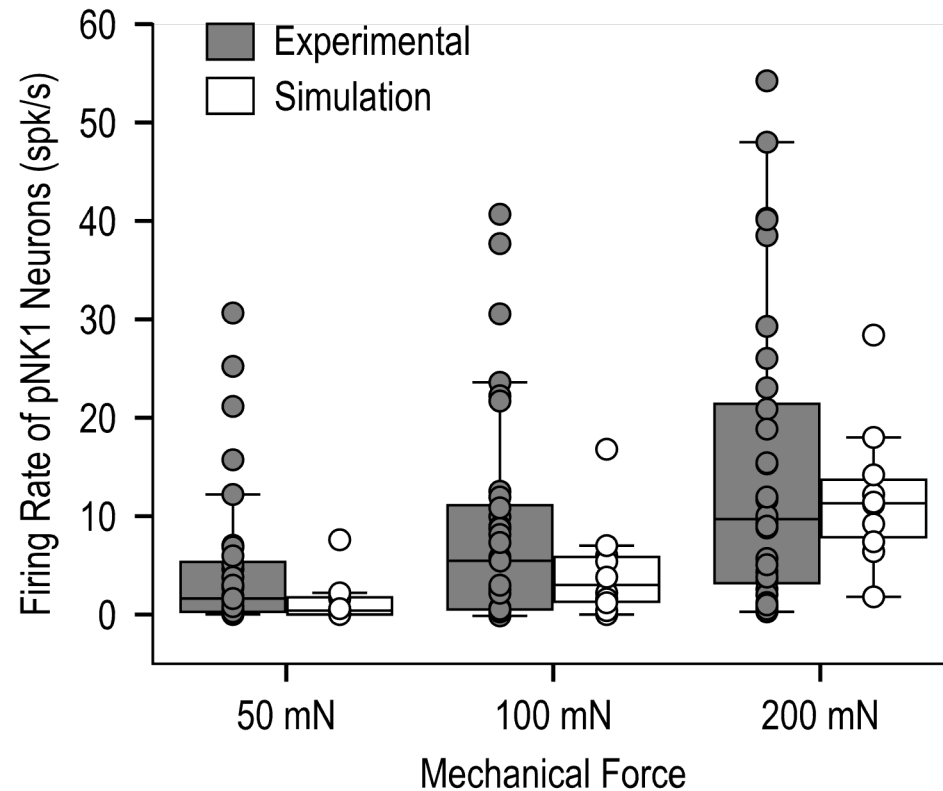

- We optimized the 35 synaptic weights using a genetic algorithm

Result 1: The SDH model reproduces experimental responses to mechanical stimulation across multiple intensities

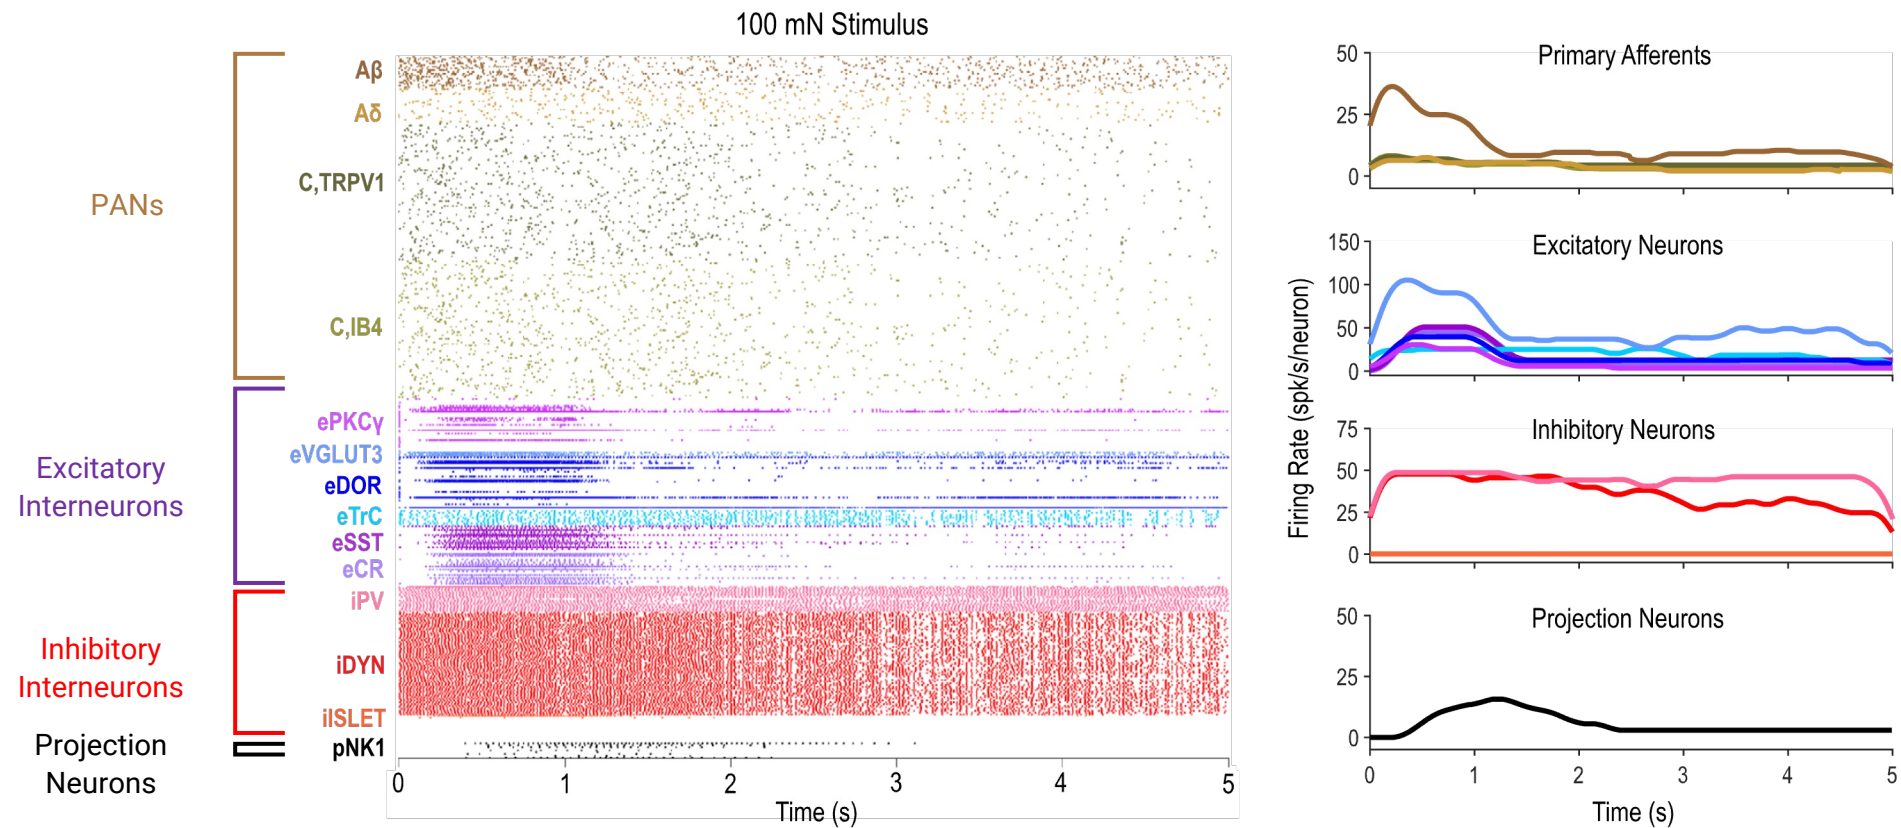

An example set of synaptic weights from the GA

Result 1: The SDH model reproduces experimental responses to mechanical stimulation across multiple intensities

Ex. Model response to 100 mN...

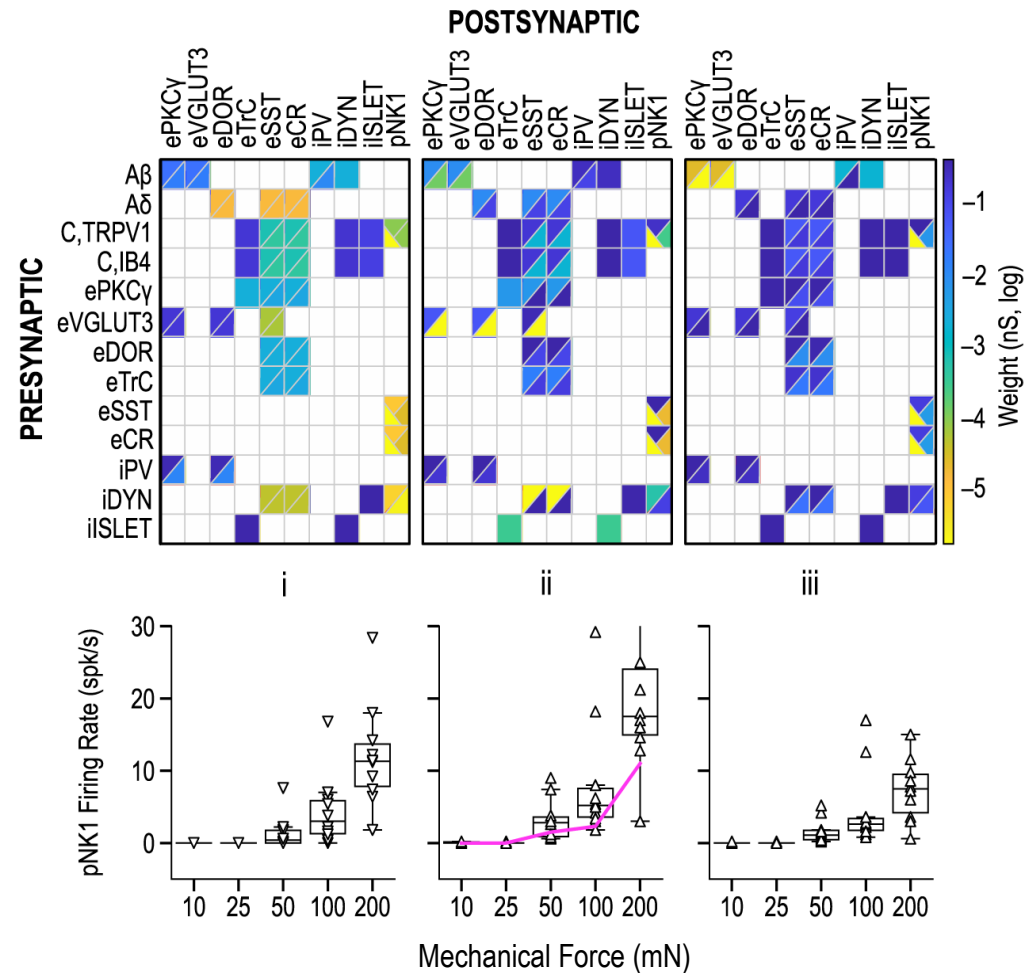

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Degeneracy → Different mechanisms that give rise to similar/nearly identical behaviour

Adapted from Marder et al. (2015)

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Different combinations of synaptic weights produce...

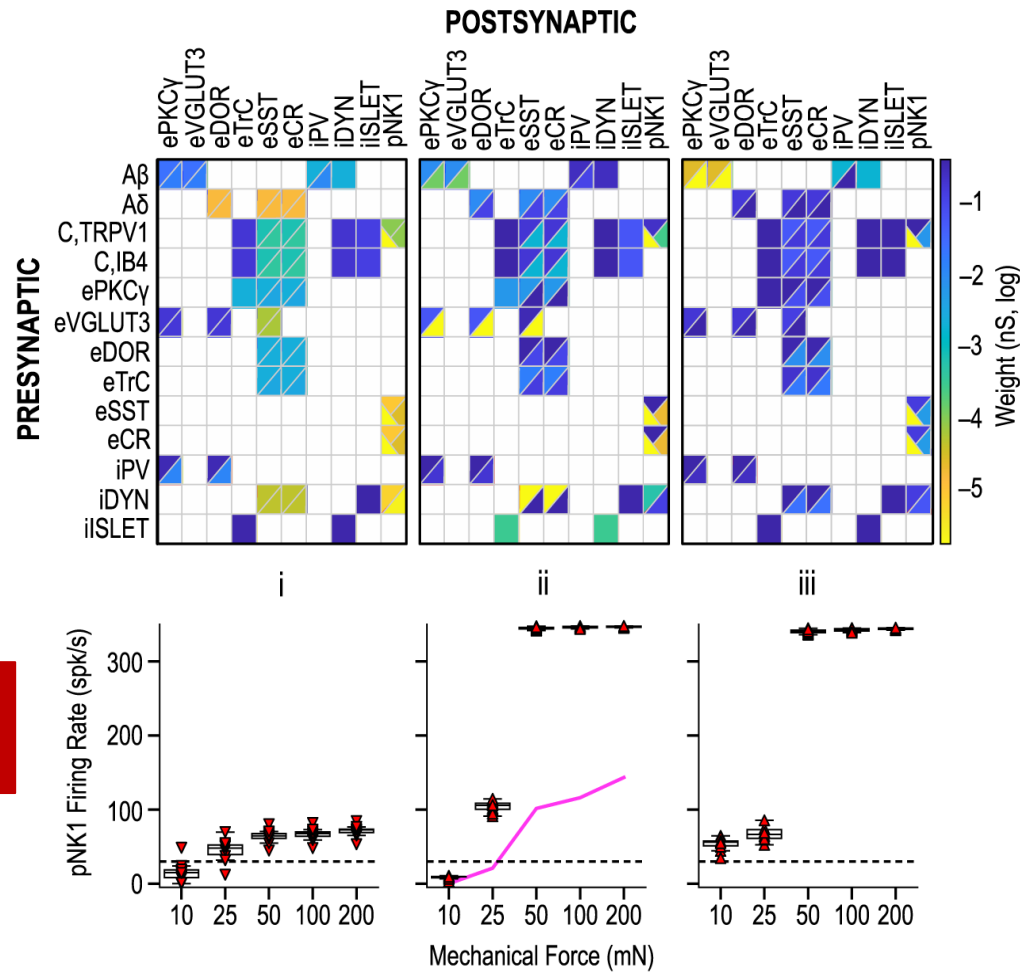

...equivalent responses to normal touch

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Adapted from Marder et al. (2015)

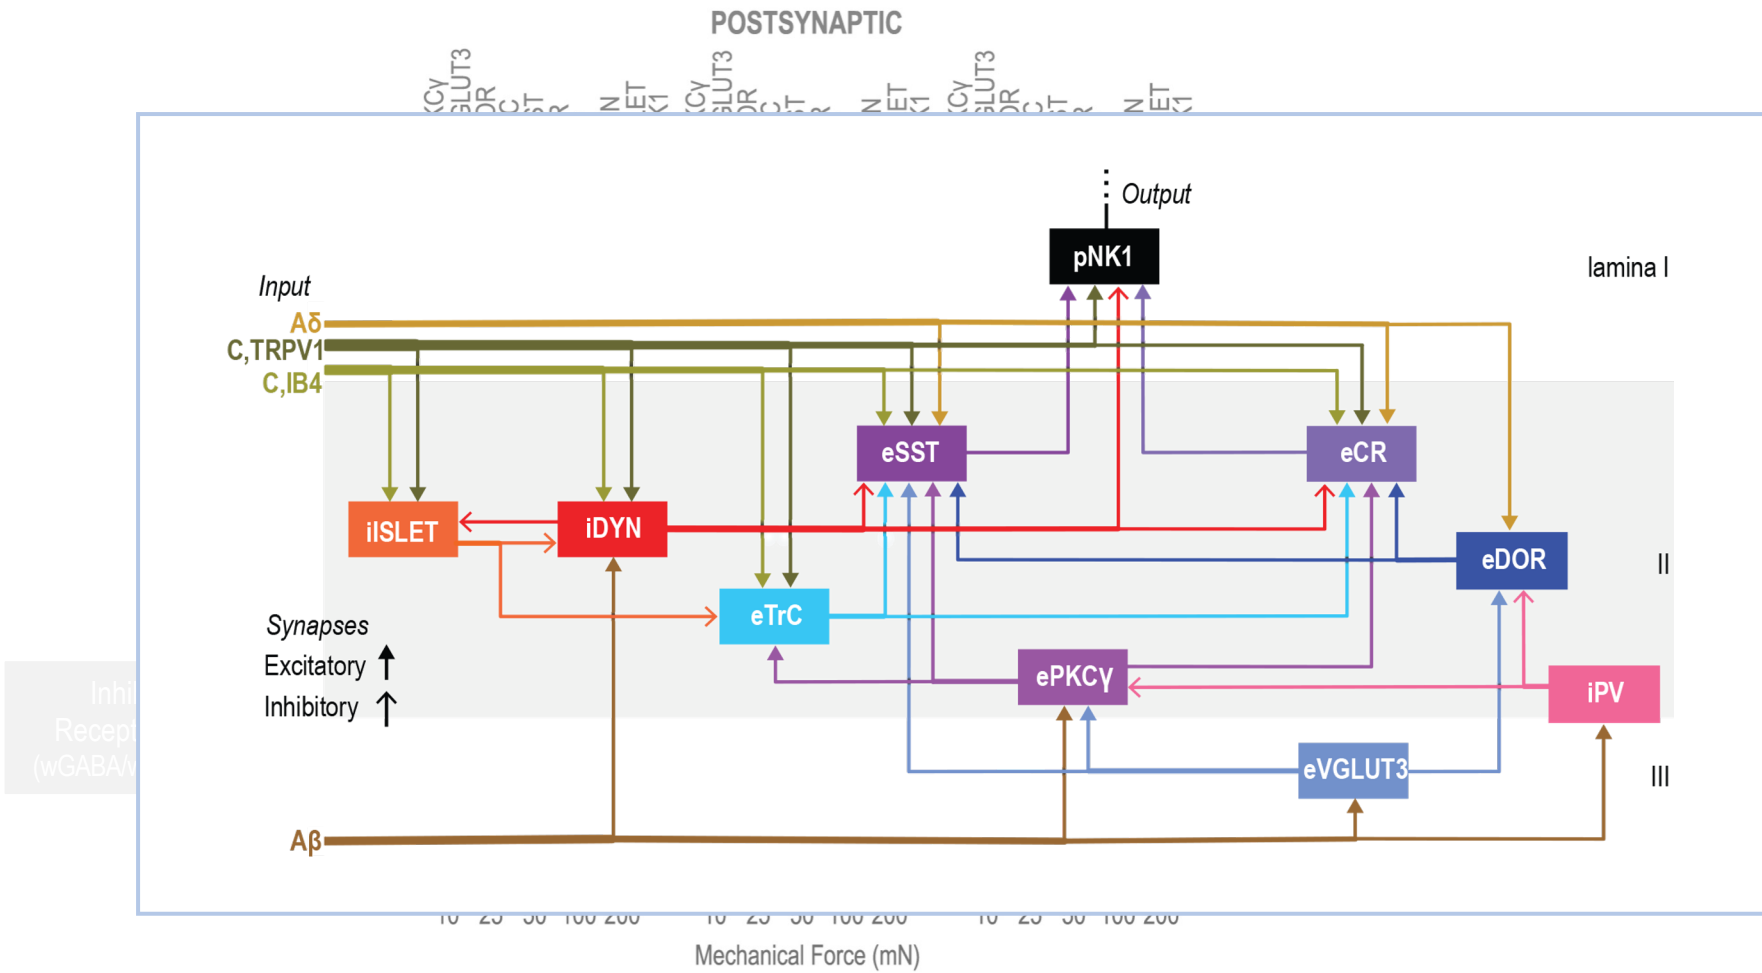

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

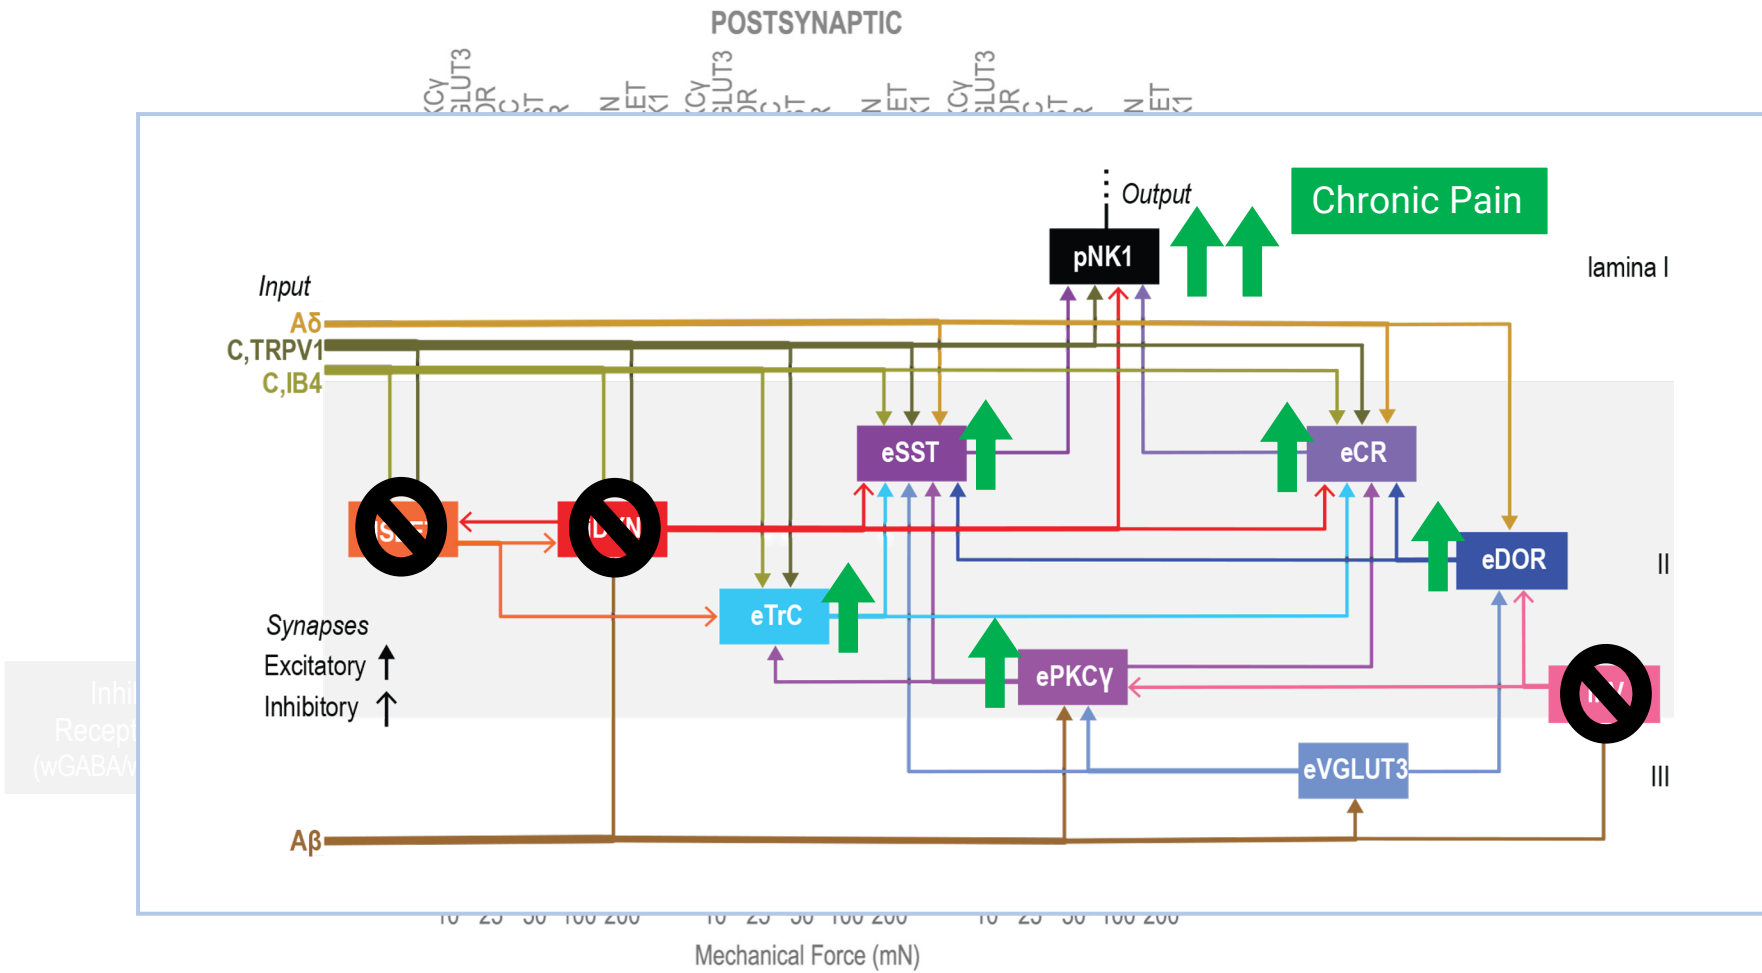

Inhibitory
Receptor Block
(wGABA/wGlycine=0)

Different combinations of synaptic weights produce...
...different responses to pathological disinhibition

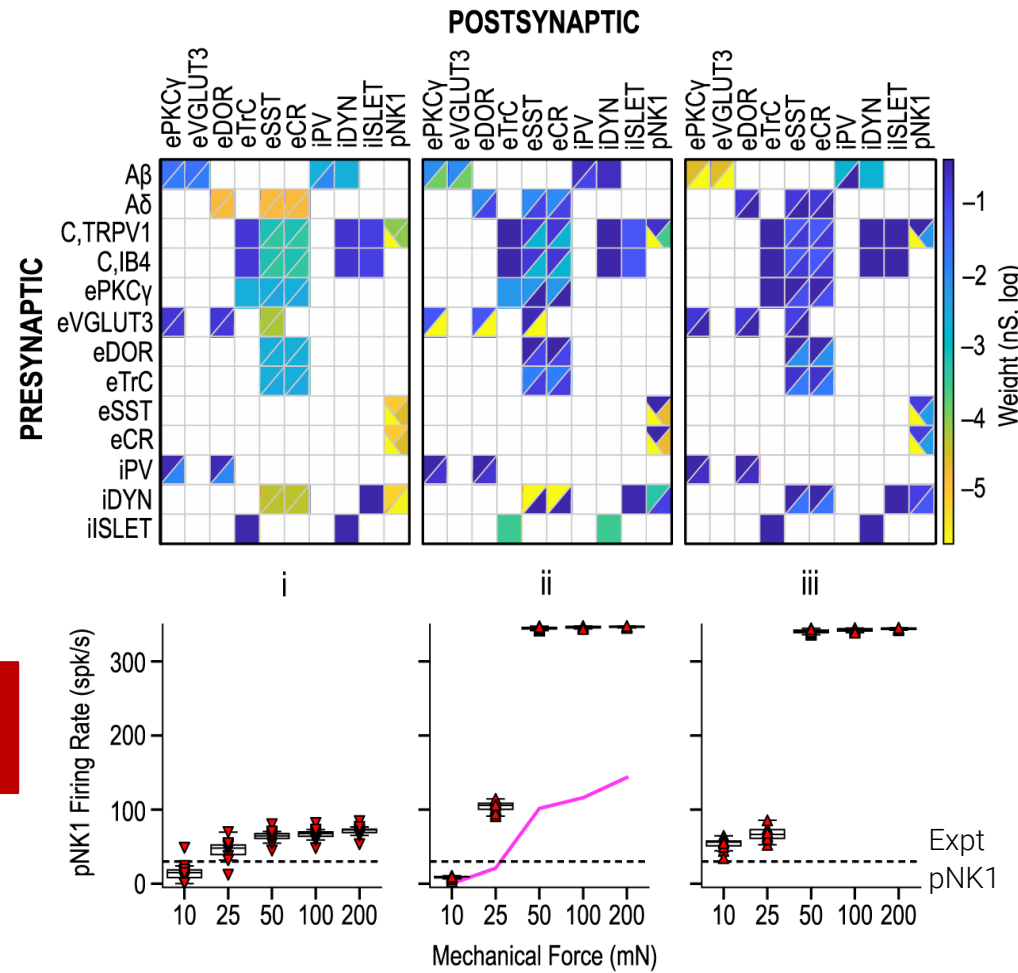

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Result 2: Disparate combinations of synaptic weights produced equivalent circuit function, revealing degeneracy in the SDH

Inhibitory Receptor Block (wGABA/wGlycine=0)

Different combinations of synaptic weights produce...

...different responses to pathological disinhibition

Also serves to validate the model!

Implications for Degeneracy in SDH

- Degeneracy in spinal circuit wiring may underlie heterogenous responses of different circuits to pathological insult or therapeutic intervention.

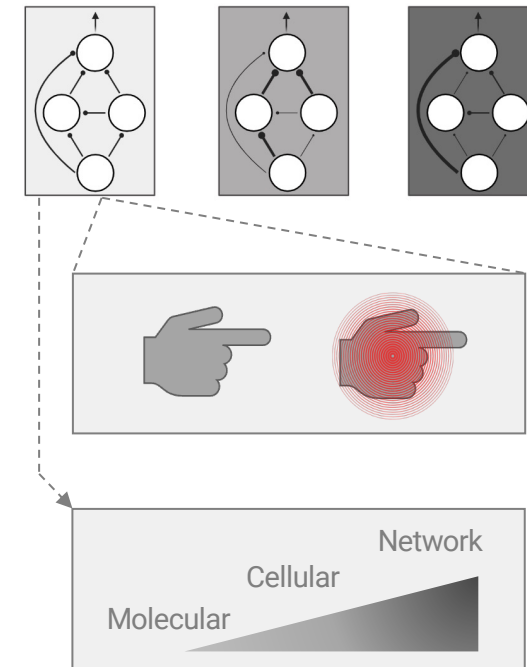

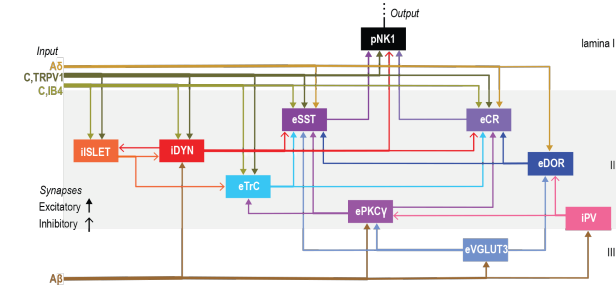

Summary & Conclusions

We have built a data-driven, multiscale model of the SDH circuit

Optimization of the model revealed circuit-level degeneracy in the SDH

Top model reproduces experimental data under normal and pathological conditions

The model provides a new tool for testing hypotheses *in silico*
